Plotting the output as a function of two different input factors

Which factor is more important?

~1,000 blue points

Divide them in 20 bins of ~ 50 points

Compute the bin's average (pink dots)

Each pink point is $\sim E_{\mathbf{x}_{\sim i}}(Y|X_i)$

Take the variance of
the pink points one
obtains a sensitivity
measure

$$V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right)$$

Which factor
has the highest
 $V_{X_i} \left(E_{\mathbf{x}_{\sim i}} (Y | X_i) \right) ?$

For additive models one can decompose the total variance as a sum of those partial variances

$$\sum_i V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right) \approx V(Y)$$

... which is also how additive models are defined

$$S_i = \frac{V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right)}{V(Y)}$$

The partial variance divided by the total variance is the so-called sensitivity index of the first order, identical in formulation to Pearson's correlation ratio

Smoothed curve:

$$\mathbf{E}_{\mathbf{x} \sim i} (y \mid x_i)$$

First order
sensitivity index:

$$\frac{V_{x_i} (\mathbf{E}_{\mathbf{x} \sim i} (y \mid x_i))}{V(y)}$$

Pearson's correlation
ratio

Smoothed curve

$$S_i \equiv \eta_i^2 := \frac{V_{x_i} (\mathbf{E}_{\mathbf{x}_{\sim i}} (y \mid x_i))}{V(y)}$$

First order sensitivity index

Unconditional
variance

Non additive models

Is $S_i = 0$?

Is this factor non-important?

There are terms which capture
two-way, three way, \cdots interactions
among variables

All these terms are linked by a
formula

Variance decomposition (ANOVA)

$$V(Y) =$$

$$\sum_i V_i + \sum_{i,j>i} V_{ij} + \dots + V_{123\dots k}$$

Variance decomposition (ANOVA)

The total variance can be decomposed into main effects and interaction effects up to the order k , the dimensionality of the problem (independent factors)

If fact interactions terms are awkward to handle: **just the second order terms** for a model with k factors are as many as $k(k-1)/2 \dots$

(10 factors=45 second order terms)

How about a single ‘importance’ terms for all effects?

In fact such terms exist and can be computed easily, without knowledge of the individual interaction terms

Thus given a model $f(X_1, X_2, \dots, X_3)$

Where the variance decomposition would

read $1 = S_1 + S_2 + S_3 + S_{12} + S_{13} + S_{23} + S_{123}$

We compute

$$T_1 = S_1 + S_{12} + S_{13} + S_{123}$$

$$T_2 = S_2 + S_{12} + S_{23} + S_{123}$$

$$T_3 = S_3 + S_{13} + S_{23} + S_{123}$$

The measures and their ‘settings’ = when to use them

The effective dimension and quasi-Monte Carlo integration[☆]

Xiaoqun Wang^{a,b,*} and Kai-Tai Fang^c

^a*Department of Mathematical Sciences, Tsinghua University, Beijing 100084, China*

^b*School of Mathematics, University of New South Wales, Sydney 2052, Australia*

^c*Department of Mathematics, Hong Kong Baptist University, Hong Kong, China*

Received 12 February 2002; accepted 6 November 2002

The difficulty of a function/model is not in its number of dimensions but in the number of effective dimensions, either in the **truncation** or **superposition** sense

truncation sense = how many factors are important?

superposition sense=how high is the highest interaction?

Why using variance-based
sensitivity analysis methods

Advantages with variance based methods:

- graphic interpretation scatterplots
- statistical interpretation
- expressed plain English (another lesson)
- working with sets (another lesson)
- relation to settings such as factor fixing and factor prioritization
- give the effective dimension

Chapter 1 its
exercises

... anyone developing a
new method tests it against S_i, T_i

Miscalculating the volumes of water withdrawn for irrigation, the largest consumer of freshwater in the world, jeopardizes sustainable water management. Hydrological models quantify water withdrawals, but their estimates are unduly precise. Model imperfections need to be appreciated to avoid policy misjudgements.

Sustainable Development Goals (SDGs), from Zero Hunger (SDG 2) to Water Stress (SDG 6), will be poorly assessed if irrigation water withdrawal convey an illusion of accuracy

Don't use Morris' method

More cumbersome and fragile than the total sensitivity index that is its close equivalent

Contents lists available at ScienceDirect

Computer Physics Communications

www.elsevier.com/locate/cpc

From screening to quantitative sensitivity analysis. A unified approach

Francesca Campolongo^{*}, Andrea Saltelli, Jessica Cariboni

Joint Research Centre, Institute for the Protection and Security of the Citizen, Ispra, Italy

Morris

Fig. 1. Example of trajectory in 3 dimensions for the original EE method.

Total sensitivity index T_i

Fig. 3. Example of a radial sample in three dimensions.

Morris needs one more design parameter than T_i :
the space step for the grid

Morris is more cumbersome to interpret (two outputs: μ and σ)

Don't confuse the map with
the territory

If you do, sensitivity analysis will not save you

Orrin H.
Pilkey

Useless Arithmetic: Why Environmental Scientists Can't Predict the Future
by Orrin H. Pilkey and Linda Pilkey-Jarvis, Columbia University Press,
2009.

<<It is important, however, to recognize that the sensitivity of the parameter in the equation is what is being determined, not the sensitivity of the parameter in nature>>

<<...If the model is wrong or if it is a poor representation of reality, determining the sensitivity of an individual parameter in the model is a meaningless pursuit>>

One of the examples discussed concerns the **Yucca Mountain** repository for radioactive waste. TSPA model (for total system performance assessment) for safety analysis.

TSPA is Composed of 286 sub-models.

TSPA (like any other model) **relies on assumptions** → one is the low permeability of the geological formation → long time for the water to percolate from surface to disposal.

The confidence of the stakeholders in TSPA was not helped when evidence was produced which could lead to an upward revision of 4 orders of magnitude of this parameter
(the ^{36}Cl story)

Type III error in sensitivity: Examples:

In the case of TSPA (Yucca mountain) a range of 0.02 to 1 millimetre per year was used for percolation of flux rate.

→... SA useless if it is instead ~ 3,000 millimetres per year.

“Scientific mathematical modelling should involve constant efforts to falsify the model”

→ Organized skepticism (as per CUDOS)

Communalism, Universalism, Disinterestedness, Organized Skepticism, from sociology of science, Robert K. Merton.

Sensitivity analysis didn't help. A practitioner's critique of the Stern review

Andrea Saltelli^{*}, Beatrice D'Hombres

Joint Research Centre, Institute for the Protection and Security of the Citizen, Ispra, Italy

The case of Stern's Review – Technical Annex to postscript

William Nordhaus,
University of Yale
Nobel 'Economics'
2018

Nicholas Stern, London School
of Economics

Stern, N., Stern Review on the Economics of Climate Change. UK Government Economic Service, London, www.sternreview.org.uk.

Nordhaus W., Critical Assumptions in the Stern Review on Climate Change, SCIENCE, 317, 201–202, (2007).

The Stern – Nordhaus exchange on *SCIENCE*

Nordhaus → attacks Stern based on ‘wrong’ range of discount rate (\sim you are GIGOing)

Stern → Perform a sensitivity analysis and retorts: ‘My analysis shows robustness’

My problems with Stern's SA:

... but foremost Stern says:
changing assumptions → important effect
when instead he should admit that:
changing assumptions → all changes a lot

How was it done? A reverse engineering of the analysis

Missing points

% loss in GDP per capita

Conclusion:

Model prediction are too uncertain to adjudicate the dispute about the urgency of action on climate change;

Both assertion (Stern) and refutation (Nordhaus) are indefensible

Same criticism applies to Nordhaus – both authors frame the debate around numbers which are ...

... precisely wrong

Peter Kennedy, A Guide to Econometrics.

One of the ten commandments of applied econometrics according to Peter Kennedy:

“Thou shall confess in the presence of sensitivity.
Corollary: Thou shall anticipate criticism “

NEVER vary all factors
of the same amount

Be it 5%, 10%, or 20%

In a numerical experiment relating to a real-life application the range of uncertainty of each input is crucial input to the analysis, and often the most expensive to get

... beside uncertainty can be used instrumentally

Don't stop at sensitivity analysis

Five ways to ensure that models serve society: a manifesto

Pandemic politics highlight how predictions need to be transparent and humble to invite insight, not blame.

Don't use just any method

➔ Use the method appropriate to context and purpose; the example of variance based / moment independent / VARS methods

Don't use One factor At a Time (OAT)

➔ Geometric proof paper plus 'why false SA' paper

Don't use method that are not model-independent (such as PCC, PRCC)

➔ Early SA papers CSDA RESS

Don't use either LHS or optimized LHS

➔ Quasi random numbers and relative papers; mind the constructive dimension (Owen, Kucherenko)

Don't run the model just once

➔ Lubarsky's cybernetic enthomology

Don't use Morris' method

➔ Dependence upon one extra design parameter plus ambiguity in interpretation (μ and σ); Paper 2011 showing superiority T_j over Morris

Don't confuse the map with the territory

➔ J.L. Borges; Yucca Mountain example; Rayner's displacement

Beware the dimension of your model

➔ The conjecture of O'Neil

Don't sample just parameters and boundary conditions

➔ Use e.g. triggers to explore the effect of other assumptions

Don't go public with your results without having seen your SA

The case of the Stern-Nordhaus controversy

NEVER vary all factors of the same amount (5%, 10%, 20%)

➔ Avoiding GIGO

Don't stop at sensitivity analysis

➔ Think about the sensitivity auditing

The End

@andreasaltelli

Question 1

The influence of the key variables should be investigated by a sensitivity analysis.

- Is something wrong about the statement above (p. 384 of EC guidelines)

Question 2

“Are the results from a particular model more sensitive to changes in the model and the methods used to estimate its parameters, or to changes in the data?” (Majone 1989)

Please comment

Question 3

What uses can you imagine for sensitivity analysis?

Presenter: Andrea Saltelli

When: June 28th, 9.30–10.30

Format: Physical

Room: 511

Summary of the talk: The way SA is mostly done in the literature is wrong. So one can introduce SA 'via negativa' (N.N. Taleb), focusing on what pitfalls should be avoided. Mathematical modelling itself can be effectively used to rule out what cannot be (e.g. in terms of policy options) so that only viable alternatives are left for further investigation. SA also helps to tackle the known tradeoff between model complexity and model error, known in ecology as the conjecture of O'Neil. This becomes particularly relevant where the model does not dispose of a validation data set, e.g. when the model is predicting in either the future or the unknown. Finally, if your friends are sociologists, they might object that even your sensitivity analysis does not go far enough because of embedded or implicit assumptions. In the talk we shall visit these eternal problems with examples.
