What is modelling?

Modelling as a craft rather than as a science for Robert Rosen

R. Rosen, *Life Itself: A Comprehensive Inquiry Into the Nature, Origin, and Fabrication of Life*. Columbia University Press, 1991.

What is a model ?

Robert Rosen

“models are most useful when they are used to challenge existing formulations, rather than to validate or verify them”

Naomi
Oreskes

N. Oreskes, K. Shrader-Frechette, and K. Belitz, “Verification, Validation, and Confirmation of Numerical Models in the Earth Sciences,” *Science*, 263, no. 5147, 1994.

Models are not physical laws

Oreskes, N., 2000, Why predict? Historical perspectives on prediction in Earth Science, in Prediction, Science, Decision Making and the future of Nature, Sarewitz et al., Eds., Island Press, Washington DC

“[...] to be of value in theory testing, the predictions involved must be capable of refuting the theory that generated them”
(N. Oreskes)

“In many cases, these temporal predictions **are treated with the same respect** that the hypothetic–deductive model of science accords to logical predictions. But this respect is largely misplaced”

“[...] models are complex amalgam of theoretical and phenomenological laws (and the governing equations and algorithms that represent them), empirical input parameters, and a model conceptualization

[...] When a model generates a prediction, of what precisely is the prediction a test? The laws? The input data? The conceptualization?

Any part (or several parts) of the model might be in error, and there is no simple way to determine which one it is”

Models are hence vulnerable to misuse, more than e.g. a physical law or a standardized statistical test ➡

- Mathematical hubris
- Lack of standards for quality control
- Forgetting the conditionality of model knowing

Presented as ‘Conjecture by O’Neill’

In M. G. Turner and R. H. Gardner,
“Introduction to Models” in Landscape
Ecology in Theory and Practice, New
York, NY: Springer New York, 2015, pp.
63–95.

Why sensitivity
analysis

Also known as Zadeh's principle of incompatibility,
whereby as complexity increases “precision and
significance (or relevance) become almost mutually
exclusive characteristics”

L. Zadeh, “Outline of a New Approach to the Analysis of Complex Systems
and Decision Processes,” IEEE Trans. Syst. Man. Cybern., vol. 3, no. 1, pp.
28–44, 1973.

Model-based knowing is
conditional

For John Kay modelling may need as input information which we don't have

Better Regulation Guidelines

These guidelines explain what Better Regulation is and how it should be applied in the day to day practices when preparing new initiatives and proposals or managing existing policies and legislation.

They cover the whole policy cycle, from policy preparation and adoption to implementation and application, to evaluation and revision of EU law. For each of these phases there are a number of Better Regulation principles, objectives, tools and procedures to make sure that the EU has the best regulation possible. These relate to planning, impact assessment, stakeholder consultation, implementation and evaluation.

The [Better Regulation Guidelines](#) are structured into chapters which cover each of the instruments of the law-making process. The corresponding [toolbox](#) gives more detailed and technical information.

Better Regulation Guidelines are based on the outcomes of public consultation exercises carried out in 2013 and 2014.

- [Public consultation on the revision of the Commission's Impact Assessment Guidelines](#)

An engineer's vision of UA, SA

One can sample more than just factors:

- modelling assumptions,
- alternative data sets,
- resolution levels,
- scenarios ...

Assumption	Alternatives
Number of indicators	<ul style="list-style-type: none">▪ all six indicators included or one-at-time excluded (6 options)
Weighting method	<ul style="list-style-type: none">▪ original set of weights,▪ factor analysis,▪ equal weighting,▪ data envelopment analysis
Aggregation rule	<ul style="list-style-type: none">▪ additive,▪ multiplicative,▪ Borda multi-criterion

Space of alternatives

x_{11}	x_{12}	...	x_{1k}
x_{21}	x_{22}	...	x_{2k}
...
x_{N1}	x_{N2}	...	x_{Nk}

Each column is a sample from the distribution of a factor

Each row is a sample trial to generate a value of y

Examples of distributions of input factors

Why sensitivity analysis

"Are the results from a particular model more sensitive to changes in the model and the methods used to estimate its parameters, or to changes in the data?"

... SA can tell

Model-based knowing is
conditional; SA makes the
conditionality evident

Why sensitivity
analysis

SA can detect garbage in
garbage out (GIGO)

Why sensitivity
analysis

Funtowicz & Ravetz's GIGO (Garbage In, Garbage Out) Science “where uncertainties in inputs must be suppressed least outputs become indeterminate”

Leamer's “Conclusions are judged to be sturdy only if the neighborhood of assumptions is wide enough to be credible and the corresponding interval of inferences is narrow enough to be useful”

S. Funtowicz and J. R. Ravetz, *Uncertainty and Quality in Science for Policy*. Dordrecht: Kluwer, 1990; E. E. Leamer, “Sensitivity Analyses Would Help,” *Am. Econ. Rev.*, vol. 75, no. 3, pp. 308–313, 1985.

Why using
variance-based
sensitivity analysis
methods

Plotting the output as a function of two different input factors

Which factor is more important?

~1,000 blue points

Divide them
in 20 bins of
~ 50 points

Compute the
bin's average
(pink dots)

Each pink point is $\sim E_{\mathbf{x}_{\sim i}}(Y|X_i)$

Take the variance of
the pink points one
obtains a sensitivity
measure

$$V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right)$$

Which factor
has the highest
 $V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right) ?$

$$S_i \equiv \frac{V\left(E\left(Y|X_i\right)\right)}{V_Y}$$

Smoothed curve:

$$\mathbf{E}_{\mathbf{x} \sim i} (y \mid x_i)$$

First order
sensitivity index:

$$\frac{V_{x_i} (\mathbf{E}_{\mathbf{x} \sim i} (y \mid x_i))}{V(y)}$$

Pearson's correlation
ratio

Smoothed curve

$$S_i \equiv \eta_i^2 := \frac{V_{x_i} (\mathbf{E}_{\mathbf{x}_{\sim i}} (y \mid x_i))}{V(y)}$$

First order sensitivity index

Unconditional
variance

$$V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right)$$

First order effect, or top marginal variance = the expected reduction in variance that would be achieved if factor X_i could be fixed.

Why?

Because:

$$V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right) + E_{X_i} \left(V_{\mathbf{X}_{\sim i}} (Y | X_i) \right) = V(Y)$$

Easy to prove using $V(Y) = E(Y^2) - E^2(Y)$

Because:

$$V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right) +$$

$+ E_{X_i} \left(\underline{V_{\mathbf{X}_{\sim i}} (Y | X_i)} \right)$

$$= V(Y)$$

This is the variance when a factor X_i is fixed ...

Because:

$$V_{X_i} \left(E_{\mathbf{x}_{\sim i}} (Y | X_i) \right) +$$

$+ E_{X_i} \left(V_{\mathbf{x}_{\sim i}} (Y | X_i) \right)$

$$= V(Y)$$

This is what variance would be left (on average) if X_i could be fixed...

... then this ...

$$\boxed{V_{X_i}(E_{\mathbf{X}_{\sim i}}(Y|X_i))} + \\ + E_{X_i}(V_{\mathbf{X}_{\sim i}}(Y|X_i)) = V(Y)$$

... must be the expected reduction
in variance that would be achieved
if factor X_i could be fixed

For additive models one can decompose the total variance as a sum of first order effects

$$\sum_i V_{X_i} \left(E_{\mathbf{X}_{\sim i}} (Y | X_i) \right) \approx V(Y)$$

... which is also how additive models are defined

Non additive models can also be effectively dealt with, in the context of variance decomposition theory

Is $S_i = 0$?

Is this factor non-important?

Variance decomposition (ANOVA)

$$V(Y) =$$

$$\sum_i V_i + \sum_{i,j>i} V_{ij} + \dots + V_{123\dots k}$$

Variance decomposition (ANOVA)

When the factors are independent the total variance can be decomposed into main effects and interaction effects up to the order k , the dimensionality of the problem.

Thus given a model $Y=f(X_1,X_2,X_3)$

Decomposition:

$$\begin{aligned} V = & V_1 + V_2 + V_3 + \\ & + V_{12} + V_{13} + V_{23} + \\ & + V_{123} \end{aligned}$$

Thus given a model $Y=f(X_1,X_2,X_3)$

Same decomposition divided by V

$$\begin{aligned} 1 &= S_1 + S_2 + S_3 + \\ &+ S_{12} + S_{13} + S_{23} + \\ &+ S_{123} \end{aligned}$$

One may be interested in the total effects:

$$S_{T1} = S_1 + S_{12} + S_{13} + S_{123}$$

(and analogue formulae for S_{T2} , S_{T3}) which can be computed without knowing S_1 , S_{12} , S_{13} , S_{123}

S_{T1} is called a total effect sensitivity index

$$E_{\mathbf{X}_{\sim i}} \left(V_{X_i} \left(Y | \mathbf{X}_{\sim i} \right) \right)$$

Total effect, or bottom marginal variance=
 = the expected variance that would be left if
 all factors but X_i could be fixed (self evident
 definition)

$$E_{\mathbf{X}_{\sim i}} \left(V_{X_i} \left(Y | \mathbf{X}_{\sim i} \right) \right)$$

Why? Because it is the complement (resp. unconditional variance) of the first order effect of non X_i

$$S_{Ti} \equiv \frac{E\left(V\left(Y|\mathbf{X}_{\sim i}\right)\right)}{V_Y}$$

What is the shortcoming
of S_{Ti} ?

Summary: advantages with variance based methods:

- graphic interpretation via scatterplots
- statistical interpretation
- expressed in plain English
- (working with sets)
- (relation to settings)

Coding S_i and S_{Ti} yourself?

Use this work:

[Saltelli, A., Annoni, P., Azzini, I., Campolongo, F., Ratto, M., Tarantola, S., 2010, Variance based sensitivity analysis of model output. Design and estimator for the total sensitivity index, Computer Physics Communications, 181, 259–270.](#)

How to generate
the random sample?

Quasi random
sequences
developed by I.M.
Sobol'

An LP_τ sequence

X_1, X_2 plane, 1000 Sobol' points

X_1, X_2 plane, 10000 Sobol' points

Sobol' sequences of quasi-random points

X1,X2 plane, 10000 Sobol' points

X1,X2 plane, 10000 random points

Sobol' sequences of quasi-random points
against random points

Why quasi-random

Sergei Kucherenko,
Imperial College London

$$\varepsilon = \left(\frac{1}{K} \sum_{k=1}^K (I[f] - I_k[f])^2 \right)^{1/2}$$

$$\sum_{i=1}^n (-1)^i \prod_{j=1}^i x_j$$

Root mean square error over $K=50$ different trials. The error refers to the numeric-versus-analytic value the integral of the function (for $n=360$) over its dominion.

Source: Kucherenko S., Feil B., Shah N., Mauntz W. The identification of model effective dimensions using global sensitivity analysis Reliability Engineering and System Safety 96 (2011) 440–449.

Secrets of sensitivity analysis

Why should one ever run a model just once?

→ While developing a model run it a few more times at a time (e.g. 16, 32,...)

The most important question is the
question

Or: sensitivity analysis is not “run”
on a model but on a model once
applied to a question

Sensitivity analysis should not be used to hide assumptions

If sensitivity analysis shows that
a question cannot be answered by
the model one should find another
question or model

[Often the love for one's own model
prevails]

Badly kept secret:

There is always one more bug!

= Lubarsky's Law of Cybernetic Entomology

Use SA to calibrate complexity

Limit of SA: the map is not
the territory

Orrin H.
Pilkey

Useless Arithmetic: Why Environmental Scientists Can't Predict the Future
by Orrin H. Pilkey and Linda Pilkey-Jarvis, Columbia University Press,
2009.

<<It is important to recognize that the sensitivity of the parameter in the equation is what is being determined, not the sensitivity of the parameter in nature.

[...] If the model is wrong or if it is a poor representation of reality, determining the sensitivity of an individual parameter in the model is a meaningless pursuit.>>

One of the examples discussed concerns the **Yucca Mountain** repository for radioactive waste. TSPA model (for total system performance assessment) for safety analysis.

TSPA is Composed of 286 sub-models.

TSPA (like any other model) **relies on assumptions** → one is the low permeability of the geological formation → long time for the water to percolate from surface to disposal.

Evidence was produced leading to an upward revision
of 4 orders of magnitude of this parameter
(the ^{36}Cl story)

In the model a range of 0.02 to 1 millimetre per year was used for percolation of flux rate.

→... SA useless if it is instead ~ 3,000 millimetres per year.

“Scientific mathematical modelling should involve constant efforts to falsify the model”

Ref. ➔ Robert K. Merton’s ‘Organized skepticism’

Communalism – the common ownership of scientific discoveries, according to which scientists give up intellectual property rights in exchange for recognition and esteem (Merton actually used the term Communism, but had this notion of communalism in mind, not Marxism);

Universalism – according to which claims to truth are evaluated in terms of universal or impersonal criteria, and not on the basis of race, class, gender, religion, or nationality;

Disinterestedness – according to which scientists are rewarded for acting in ways that outwardly appear to be selfless;

Organized Skepticism – all ideas must be tested and are subject to rigorous, structured community scrutiny.

Robert K. Merton

Limit of SA: Often no SA or
wrong kind of SA applied

When All Models Are Wrong

BY ANDREA SALTELLI, SILVIO FUNTOWICZ

The rules of sensitivity auditing

1. Check against rhetorical use of mathematical modelling;
2. Adopt an “assumption hunting” attitude; focus on unearthing possibly implicit assumptions;
3. Check if uncertainty been instrumentally inflated or deflated.

4. Find sensitive assumptions before these find you; do your SA before publishing;
5. Aim for transparency; Show all the data;
6. Do the right sums, not just the sums right;
7. Perform a proper global sensitivity analysis.
